# CSC 591 Systems Attacks and Defenses

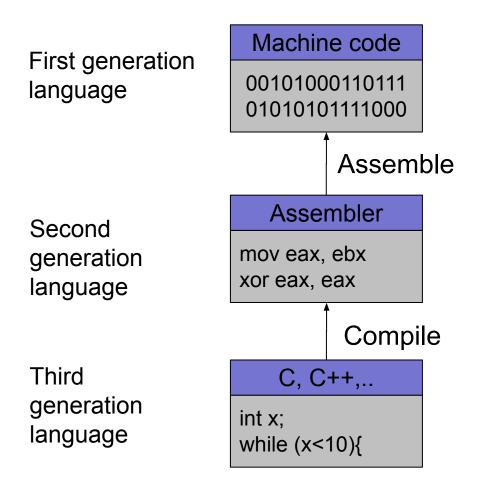

## **Reverse Engineering**

Alexandros Kapravelos akaprav@ncsu.edu

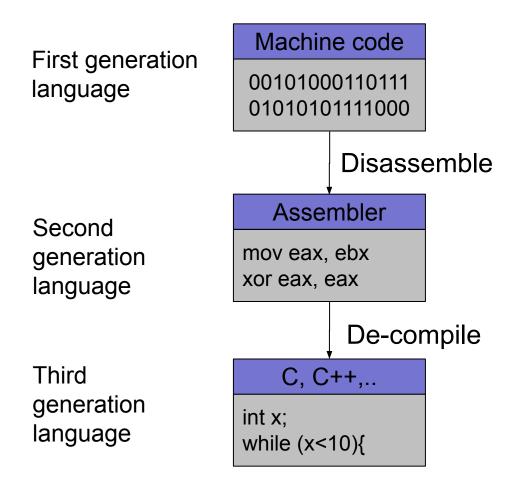

## Introduction

- Reverse engineering
  - process of analyzing a system
  - understand its structure and functionality
  - used in different domains (e.g., consumer electronics)
- Software reverse engineering
  - understand architecture (from source code)
  - extract source code (from binary representation)
  - change code functionality (of proprietary program)
  - understand message exchange (of proprietary protocol)

## **Software Engineering**

#### **Software Reverse Engineering**

# **Going Back is Hard!**

- Fully-automated disassemble/de-compilation of arbitrary machine-code is theoretically an **undecidable problem**
- Disassembling problems
  - hard to distinguish code (instructions) from data
- De-compilation problems
  - structure is lost
    - data types are lost, names and labels are lost
  - no one-to-one mapping
    - same code can be compiled into different (equivalent) assembler blocks
    - assembler block can be the result of different pieces of code

# **Why Reverse Engineering**

- Software interoperability
  - Samba (SMB Protocol)
  - OpenOffice (MS Office document formats)
- Emulation
  - Wine (Windows API)
  - React-OS (Windows OS)
- Legacy software
  - Onlive
- Malware analysis
- Program cracking
- Compiler validation

# **Analyzing a Binary - Static Analysis**

- Identify the file type and its characteristics
  - architecture, OS, executable format...
- Extract strings
  - commands, password, protocol keywords...
- Identify libraries and imported symbols
  - network calls, file system, crypto libraries
- Disassemble
  - program overview
  - finding and understanding important functions
    - by locating interesting imports, calls, strings...

# Analyzing a Binary - Dynamic Analysis

- Memory dump
  - extract code after decryption, find passwords...
- Library/system call/instruction trace
  - determine the flow of execution
  - interaction with OS
- Debugging running process
  - inspect variables, data received by the network, complex algorithms..
- Network sniffer
  - find network activities
  - understand the protocol

- Gathering program information
  - get some rough idea about binary (file)

```
linux util # file sil
sil: ELF 32-bit LSB executable, Intel 80386, version 1
(SYSV), for GNU/Linux 2.6.9, dynamically linked (uses s
hared libs), not stripped
```

- strings that the binary contains (strings)

```
linux util # strings sil | head -n 5
/lib/ld-linux.so.2
_Jv_RegisterClasses
_gmon_start__
libc.so.6
puts
```

#### **NC STATE UNIVERSITY**

# **Static Techniques**

- Examining the program (ELF) header (elfsh)
- readelf

[ELF HEADER]
[Object sil, MAGIC 0x464C457F]

| Architecture                                      | :           | Intel 80386            | ELF Version                   | :        | 1            |

Program entry point

- Used libraries

   easier when program is dynamically linked (Idd)

   linux util # ldd sil

   linux-gate.so.1 => (0xffffe000)
   libc.so.6 => /lib/libc.so.6 (0xb7e99000)
   /lib/ld-linux.so.2 (0xb7fcf000)
  - more difficult when program is statically linked

```
linux util # gcc -static -o sil-static simple.c
linux util # ldd sil-static
not a dynamic executable
linux util # file sil-static
sil-static: ELF 32-bit LSB executable, Intel 80386, version 1
(SYSV), for GNU/Linux 2.6.9, statically linked, not stripped
```

Looking at linux-gate.so.1

```
linux util # cat /proc/self/maps | tail -n 1
ffffe000-fffff000 r-xp 00000000 00:00 0
                                               [vdso]
linux util # dd if=/proc/self/mem of=linux-gate.dso bs=4096 skip=1048574
count=1 2> /dev/null
linux util # objdump -d linux-gate.dso | head -n 11
linux-gate.dso: file format elf32-i386
Disassembly of section .text:
ffffe400 < kernel vsyscall>:
ffffe400:
               51
                                      push
                                             %ecx
               52
ffffe401:
                                      push
                                             %edx
               55
                                      push
                                             %ebp
ffffe402:
              89 e5
ffffe403:
                                             %esp,%ebp
                                      mov
ffffe405:
              0f 34
                                      sysenter
```

- Used library functions
  - again, easier when program is dynamically linked (nm -D)

linux util # nm -D sil | tail -n8
 U fprintf
 U fwrite
 U getopt
 U opendir
08049bb4 B optind
 U puts
 U readdir
08049bb0 B stderr

- more difficult when program is statically linked

```
linux util # nm -D sil-static
nm: sil-static: No symbols
linux util # ls -la sil*
-rwxr-xr-x 1 root chris 8017 Jan 21 20:37 sil
-rwxr-xr-x 1 root chris 544850 Jan 21 20:58 sil-static
```

Recognizing libraries in statically-linked programs

- Basic idea
  - create a checksum (hash) for bytes in a library function
- Problems
  - many library functions (some of which are very short)
  - variable bytes due to dynamic linking, load-time patching, linker optimizations
- Solution
  - more complex pattern file
  - uses checksums that take into account variable parts
  - implemented in IDA Pro as:

Fast Library Identification and Recognition Technology (FLIRT)

- Program symbols
  - used for debugging and linking
  - function names (with start addresses)
  - global variables
  - use nm to display symbol information
  - most symbols can be removed with strip
- Function call trees
  - draw a graph that shows which function calls which others
  - get an idea of program structure

Displaying program symbols

```
linux util # nm sil | grep " T"
080488c7 T __i686.get_pc_thunk.bx
08048850 T __libc_csu_fini
08048860 T __libc_csu_init
08048904 T _fini
08048904 T _fini
08048500 T _start
08048500 T _start
080485cd T display_directory
080486bd T main
080485a4 T usage
linux util # strip sil
linux util # nm sil | grep " T"
nm: sil: no symbols
```

- Disassembly
  - process of translating binary stream into machine instructions
- Different level of difficulty
  - depending on ISA (instruction set architecture)
- Instructions can have
  - fixed length
    - more efficient to decode for processor
    - RISC processors (SPARC, MIPS, ARM)
  - variable length
    - use less space for common instructions
    - CISC processors (Intel x86)

This will backfire in the future :)

- Fixed length instructions
  - easy to disassemble
  - take each address that is multiple of instruction length as instruction start
  - even if code contains data (or junk), all program instructions are found
- Variable length instructions
  - more difficult to disassemble
  - start addresses of instructions not known in advance
  - different strategies
    - linear sweep disassembler
    - recursive traversal disassembler
  - disassembler can be desynchronized with respect to actual code

- Linear sweep disassembler
  - start at beginning of code (.text) section
  - disassemble one instruction after the other
  - assume that well-behaved compiler tightly packs instructions
  - objdump -d uses this approach

#### Let's break LSD

```
#include <stdio.h>
```

```
int main() {
    printf("Hello, world!\n");
    return 0;
}
$ gcc hello.c -o hello
$ ./hello
Hello, world!
```

## **Objdump disassembly**

#### Let's patch the program

\$ radare2 -Aw hello
[0x08048310]> 0x08048419
[0x08048419]> wx eb01 #(jmp 0x804841c)

We patched a 3-byte instruction with a 2-byte instruction. What is going to happen now with disassembly?!

#### **Disassembly fails!**

- Recursive traversal disassembler
  - aware of control flow
  - start at program entry point (e.g., determined by ELF header)
  - disassemble one instruction after the other, until branch or jump is found
  - recursively follow both (or single) branch (or jump) targets
  - not all code regions can be reached
    - indirect calls and indirect jumps
    - use a register to calculate target during run-time
  - for these regions, linear sweep is used
  - IDA Pro uses this approach

- General information about a process
  - /proc file system
  - /proc/<pid>/ for a process with pid <pid>
  - interesting entries
    - cmdline (show command line)
    - environ (show environment)
    - maps (show memory map)
    - fd (file descriptor to program image)
- Interaction with the environment
  - filesystem
  - network

- Filesystem interaction
  - lsof
  - lists all open files associated with processes
- Windows Registry
  - regmon (Sysinternals)
- Network interaction
  - check for open ports
    - processes that listen for requests or that have active connections
    - netstat
    - also shows UNIX domain sockets used for IPC
  - check for actual network traffic
    - tcpdump
    - ethereal/wireshark

- System calls
  - are at the boundary between user space and kernel
  - reveal much about a process' operation
  - strace
  - powerful tool that can also
    - follow child processes
    - decode more complex system call arguments
    - show signals
  - works via the ptrace interface
- Library functions
  - similar to system calls, but dynamically linked libraries
  - ltrace

- Execute program in a controlled environment
  - sandbox / debugger
- Advantages
  - can inspect actual program behavior and data values
  - (at least one) target of indirect jumps (or calls) can be observed
- Disadvantages
  - may accidentally launch attack/malware
  - anti-debugging mechanisms
  - not all possible traces can be seen

- Debugger
  - breakpoints to pause execution
    - when execution reaches a certain point (address)
    - · when specified memory is access or modified
  - examine memory and CPU registers
  - modify memory and execution path
- Advanced features
  - attach comments to code
  - data structure and template naming
  - track high level logic
    - file descriptor tracking
  - function fingerprinting

- Debugger on x86 / Linux
  - use the ptrace interface
- ptrace
  - allows a process (parent) to monitor another process (child)
  - whenever the child process receives a signal, the parent is notified
  - parent can then
    - access and modify memory image (peek and poke commands)
    - access and modify registers
    - deliver signals
  - ptrace can also be used for system call monitoring

- Breakpoints
  - hardware breakpoints
  - software breakpoints
- Hardware breakpoints
  - special debug registers (e.g., Intel x86)
  - debug registers compared with PC at every instruction
- Software breakpoints
  - debugger inserts (overwrites) target address with an int 0x03 instruction
  - interrupt causes signal SIGTRAP to be sent to process
  - debugger
    - gets control and restores original instruction
    - single steps to next instruction
    - re-inserts breakpoint

# **Anti-Disassembly**

- Against static analysis (disassembler)
- Confusion attack
  - targets linear sweep disassembler
  - insert data (or junk) between instructions and let control flow jump over this garbage
  - disassembler gets desynchronized with true instructions

# **Anti-Disassembly**

- Advanced confusion attack
  - targets recursive traversal disassembler
  - replace direct jumps (calls) by indirect ones (branch functions)
  - force disassembler to revert to linear sweep, then use previous attack

# **Anti-Debugging**

- Against dynamic analysis (debugger)
  - debugger presence detection techniques
    - API based
    - thread/process information
    - registry keys, process names, ...
  - exception-based techniques
  - breakpoint detection
    - software breakpoints
    - hardware breakpoints
  - timing-based and latency detection

# **Anti-Debugging**

Debugger presence checks

- Linux
  - a process can be traced only once if (ptrace(PTRACE\_TRACEME, 0, 1, 0) < 0) exit(1);
- Windows
  - API calls

OutputDebugString()

- IsDebuggerPresent()
- ... many more ...
- thread control block
  - read debugger present bit directly from process memory

# **Anti-Debugging**

**Exception-based techniques** 

```
SetUnhandledExceptionFilter()
```

After calling this function, if an exception occurs in a process that is not being debugged, and the exception makes it to the unhandled exception filter, that filter will call the exception filter function specified by the lpTopLevelExceptionFilter parameter. [ source: MSDN ]

– Idea

set the top-level exception filter, raise an unhandled exception, continue in the exception filter function

# **Anti-Debugging**

**Breakpoint detection** 

- detect software breakpoints
  - look for int 0x03 instructions
     if ((\*(unsigned \*)((unsigned)<addr>+3) & 0xff)==0xcc)
     exit(1);
  - checksum the code

```
if (checksum(text_segment) != valid_checksum)
    exit(1);
```

- detect hardware breakpoints
  - use the hardware breakpoint registers for computation

# **Reverse Engineering**

#### Goals

- focused exploration
- deep understanding
- Case study
  - copy protection mechanism
  - program expects name and serial number
  - when serial number is incorrect, program exits
  - otherwise, we are fine
- Changes in the binary
  - can be done with hexedit or radare2

# **Reverse Engineering**

- Focused exploration
  - bypass check routines
  - locate the point where the failed check is reported
  - find the routine that checks the serial number
  - find the location where the results of this routine are used
  - slightly modify the jump instruction
- Deep understanding
  - key generation
  - locate the checking routine
  - analyze the disassembly
  - run through a few different cases with the debugger
  - understand what check code does and develop code that creates appropriate keys

Static analysis vs. dynamic analysis

- Static analysis
  - code is not executed
  - all possible branches can be examined (in theory)
  - quite fast
- Problems of static analysis
  - undecidable in general case, approximations necessary
  - binary code typically contains very little information
    - functions, variables, type information, ...
  - disassembly difficult (particularly for Intel x86 architecture)
  - obfuscated code, packed code
  - self-modifying code

- Dynamic analysis
  - code is executed
  - sees instructions that are actually executed
- Problems of dynamic analysis
  - single path (execution trace) is examined
  - analysis environment possibly not invisible
  - analysis environment possibly not comprehensive
- Possible analysis environments
  - instrument program
  - instrument operating system
  - instrument hardware

#### Instrument program

- analysis operates in same address space as sample
- manual analysis with debugger
- Detours (Windows API hooking mechanism)
- binary under analysis is modified
  - breakpoints are inserted
  - functions are rewritten
  - debug registers are used
- not invisible, malware can detect analysis
- can cause significant manual effort

- Instrument operating system
  - analysis operates in OS where sample is run
  - Windows system call hooks
  - invisible to (user-mode) malware
  - can cause problems when malware runs in OS kernel
  - limited visibility of activity inside program
    - cannot set function breakpoints
- Virtual machines
  - allow to quickly restore analysis environment
  - might be detectable (x86 virtualization problems)

#### Instrument hardware

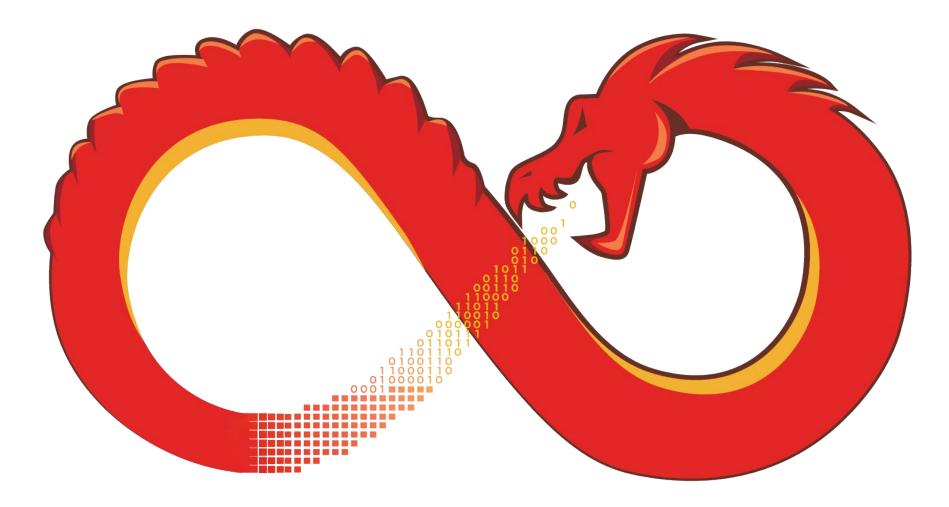

- provide virtual hardware (processor) where sample can execute (sometimes including OS)
- software emulation of executed instructions
- analysis observes activity "from the outside"
- completely transparent to sample (and guest OS)
- operating system environment needs to be provided
- limited environment could be detected
- complete environment is comprehensive, but slower
- Anubis uses this approach

### **Stealthiness**

- One obvious difference between machine and emulator
   → time of execution
- Time could be used to detect such system
  - $\rightarrow$  emulation allows to address these issues
  - → certain instructions can be dynamically modified to return innocently looking results
  - $\rightarrow$  for example, RTC (real-time clock) RDTSC instruction

# Challenges

- Reverse engineering is difficult by itself
  - a lot of data to handle
  - low level information
  - creative process, experience very valuable
  - tools can only help so much
- Additional challenges
  - compiler code optimization
  - code obfuscation
  - anti-disassembly techniques
  - anti-debugging techniques

## Ghidra

- Released in March 2019
- NSA
- open source
  - <u>https://github.com/NationalSecurityAgency/ghidra</u>
- In development for ~20 years
- Scripting in Java and Python
- Headless Analyzer
- <u>https://github.com/NationalSecurityAgency/ghidra/wiki/fil</u> <u>es/recon2019.pdf</u>
